1.

In the two previous videos, we have shown the short mathematical proofs for the Taylor series, and for special cases when the starting point is x=0, the Maclaurin series. In these set of questions, we will begin to work on applying the Taylor and Maclaurin series formula to obtain approximations of

For the function  $f(x) = e^{x^2}$  about x = 0, using the the Maclaurin series formula, obtain an approximation up to the first three non zero terms.

$$f(x)=1+x^2+rac{x^4}{2}+\ldots$$

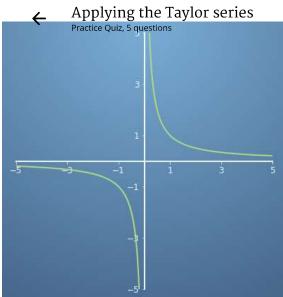

We find that only even powers of x appear in the Taylor approximation for this function.

$$f(x) = 1 + 2x + \frac{x^2}{2} + \dots$$

- $f(x)=x^2+\tfrac{x^4}{2}+\tfrac{x^6}{6}+\dots$

point

Use the Taylor series formula to approximate the first three terms of the function f(x) = 1/x, expanded around the point p = 4.

$$f(x) = -rac{1}{4} rac{(x+4)}{16} rac{(x+4)^2}{64} \cdots$$

$$f(x) = rac{(x-4)}{16} + rac{(x-4)^2}{64} - rac{(x-4)^3}{256} \cdots$$

$$f(x) = rac{1}{4} - rac{(x+4)}{16} + rac{(x+4)^2}{64} + \dots$$

$$f(x) = rac{1}{4} - rac{(x-4)}{16} + rac{(x-4)^2}{64} + \dots$$

### Correct

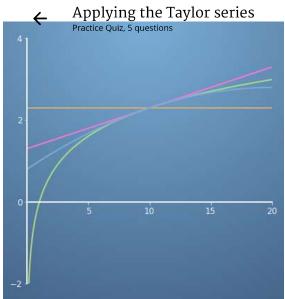

We find that only even powers of x appear in the Taylor approximation for this function.

point

By finding the first three terms of the Taylor series shown above for the function  $f(x) = \ln(x)$  (green line) about x = 10, determine the difference of using the second order taylor expansion against the first order Taylor expansion when approximating to find the value of f(2).

- $\Delta f(2) = 0.5$
- $\Delta f(2) = 0$
- $\Delta f(2) = 1.0$
- $\Delta f(2) = 0.32$

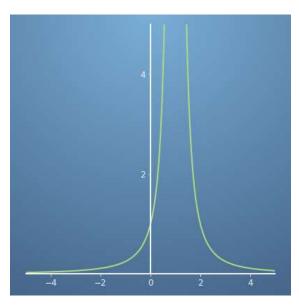

## Correct

The second order Taylor approximation about the point x=10 is  $f(x)=ln(10)+rac{(x-10)}{10}-rac{(x-10)^2}{200}\dots$ , substituting in x=2 gives us  $\Delta f(2) = 0.32$ 

1/1 point

In some cases, a Taylor series can be expressed in a general equation that allows us to find a particular  $n^{th}$  term of our series. For example the function  $f(x) \leftarrow x^x$  has applying the Taylor  $x = x^x$ . Therefore if we want to find the  $x^x$  term in our Taylor series,  $x = x^x$  into the general equation  $x = x^x$  that  $x = x^x$  is  $x = x^x$  term in our Taylor series,  $x = x^x$  into the general equation  $x = x^x$  is  $x = x^x$ . Now let us try a further working example of using general equations with Taylor series.

By evaluating the function  $f(x) = \frac{1}{(1-x)^2}$  about the origin x = 0, determine which general equation for the  $n^{th}$  order term correctly represents f(x).

$$\int f(x) = \sum_{n=0}^{\infty} (1+2n)(x)^n$$

$$\int f(x) = \sum_{n=0}^{\infty} (2+n)(x)^n$$

$$\int \int f(x) = \sum_{n=0}^{\infty} (1+n)x^n$$

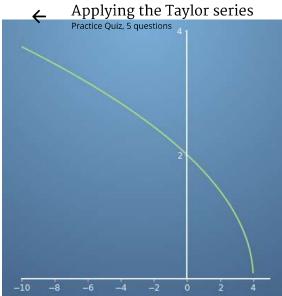

# Correct

By doing a Maclaurin series approximation, we obtain  $f(x)=1+2x+3x^2+4x^3+5x^4+\ldots$ , which satisfies the general equation shown.

$$f(x)=\sum_{n=0}^{\infty}(1+n)(-x)^n$$

1/1 point

By evaluating the function  $f(x)=\sqrt{4-x}$  at x=0 , find the quadratic equation that approximates this function.

$$f(x)=rac{x}{4} rac{x^2}{64} \cdots$$

### Correct

The quadratic equation shown is the second order approximation.

$$f(x) = 2 - x - \frac{x^3}{64\cdots}$$
